Overview of protein purification and characterization

Abstract. The efficient large scale production of recombinant proteins depends on the careful conditioning of the protein as it is isolated and purified to homogeneity. Low protein stability leads to low purification yields as a result of protein degradation, precipitation and folding instability. It is often necessary to go through several iterations of trial-and-error to optimize the homogeneity, stability and solubility of the protein sample.

Knowledge of the three-dimensional structure of a protein is absolutely required for the complete understanding of its function. The spatial orientation of amino acids in the active site of an enzyme demonstrates how substrate specificity is defined, and assists the medicinal chemist in the design of specific, tight-binding inhibitors. The shape and contour of a protein surface hints at its interaction with other proteins and with its environment. Structural analysis of multiprotein complexes helps to define the role and interaction of each individual component, and can predict the consequences of protein mutation or conditions that promote dissociation and rearrangement of the complex. Determining the three-dimensional structure of a protein requires

milligram quantities of pure material. Such quantities are required to refine crystallization conditions for X-ray analysis, or to overcome the sensitivity limitations of NMR spectroscopy. Historically, structural determination of proteins was limited to those expressed naturally in large amounts, or derived from a tissue or cell source inexpensive enough to warrant the use of large quantities of cells. However, with the advent of the techniques of modern gene expression, many proteins that are constitutively expressed in minute amounts can become accessible to large-scale purification and structural analysis.
